Use of Browser Shortcut Icon with TikiWiki.

Some web browsers can display small icons for web pages, such as in the location bar or shortcut lists. Microsoft Internet Explorer by default looks for this at `/favicon.ico`, so it also is called `favicon`.

Browsers can be told where to find the shortcut icon by including that information in the `<head>` section of a web page. If this link to a shortcut icon is defined but the icon file does not exist, the browser might display a null icon.

In TikiWiki, every page on a site can specify a single shortcut icon by inserting the following in `templates/header.tpl` just ahead of `</head>`. If using several domains on a TikiWiki server, there will be a directory for each domain in the `templates` directory. The `header.tpl` file can be copied to such a directory, which allows different icons to be specified for each domain. The icon can be defined as being in a different location than `/favicon.ico`.

```html
<link REL="shortcut icon" HREF="/favicon.ico" TYPE="image/x-icon">
```

At present TikiWiki has no support for administration of shortcut icons, so that template file has to be altered.

Although some browsers may ask only for `/favicon.ico`, in the root directory for the web server, the web server may be able to alter the request. For example, Apache can test the domain name and direct a request to an appropriate file.

In the Apache configuration file, to direct three subdomains to different directories:

```apache
### Rewrite rules for subdomains
# Test that the host name begins with the desired subdomain.
# Test if the request is for /favicon.ico.
# If true, Rewrite favicon to domain's location, and leave these rules.
RewriteCond %{HTTP_HOST}     ^public.*
RewriteCond %{REQUEST_URI}   ^/favicon.ico$
RewriteRule ^/favicon.ico   /public/favicon.ico [L]
RewriteCond %{HTTP_HOST}     ^member.*
RewriteCond %{REQUEST_URI}   ^/favicon.ico$
RewriteRule ^/favicon.ico   /member/favicon.ico [L]
RewriteCond %{HTTP_HOST}     ^staff.*
RewriteCond %{REQUEST_URI}   ^/favicon.ico$
RewriteRule ^/favicon.ico   /staff/favicon.ico [L]
```
